

TECHNICAL CASE · BUILDER

Smart Reactivation of the Customer Base

Context

Ume is a credit business with mostly offline acquisition: Ume-paid promoters and salespeople at partner retailers sign customers up in-store. In about three minutes, the customer knows whether they were approved and can start buying right away, using the credit at any partner retailer. Ume makes money in two ways: a processing fee on sales volume made with Ume credit, and interest revenue on the amount lent.

Ume's most valuable asset is the customer base it has already built — and a large part of it is dormant. You'll receive two fictional datasets that reflect the real behavior of the business (Customer Base and Retail Base), plus cost and revenue assumptions.

The problem

This is literally how it reaches you:

"We have almost 200,000 registered customers and only a fraction ever comes back to buy. Every reactivation campaign today is a guess: someone exports a spreadsheet, picks a few customers by gut feel, blasts a WhatsApp message to everyone, and by the end of the month nobody can say whether it made money or burned it. I need to stop guessing."

— Head of Growth, Ume

The request is vague on purpose. It mixes several problems — who to target, through which channel, whether it's worth it, how to know it worked — and doesn't define what "solving it" means. Structuring that ambiguity is the first part of your job — don't jump straight to a solution.

YOUR MISSION, IN ONE SENTENCE

Turn Ume's dormant customer base into actionable, proven reactivation decisions: build something that decides WHO to target, THROUGH WHICH channel, and demonstrates — with numbers — that the return outweighs the cost.

You have full autonomy over the solution: a segmentation tool, a decision engine, a campaign simulator, an agent — whatever you can make a case for. There's no single right answer: we evaluate the quality of your reasoning, the creativity of your hypotheses, and your ability to turn it into something concrete and measurable.

On using AI

This case was designed to be impossible to solve by hand — the dataset has around 200,000 rows and you have only a few days. Use AI end to end: to explore the data, reason through the problem, write code, and build the prototype (Claude, ChatGPT, Cursor, Lovable, v0, whatever you prefer).

We are not evaluating your ability to write pretty prompts. We're evaluating how you use AI to learn fast and make better decisions.

The prototype does not need to be perfect. What we evaluate is the path: how you framed the problem, what you tested, what you discarded, and why. A simple prototype with clear reasoning beats a polished

demo with no substance behind it. Include a short decision log alongside your submission.

Main failure mode — the "Demo Maker": a pretty prototype full of charts that doesn't measure impact and doesn't change a single decision isn't a solution — it's activity disguised as progress. No measured result, no experiment.

What we expect from you

Five stages, following the logic of any good experiment: understand, structure, build, measure, hand off. Document Stages 0, 1, 2 and 4 in a short write-up (including the decision log); Stage 3 is the prototype itself.

Stage 0 — Framing

Rewrite the vague request as a clear, bounded problem: which problem you chose to solve (and why that scope, not another), what you're explicitly NOT solving, and how you'll know you solved it — the success metric.

Stage 1 — Reading the data

Explore both datasets with AI before proposing a solution: what the data actually says (how many customers, in what state, what fraction is truly dormant), how you'd segment the dormant base in a way that helps decide who's worth re-engaging, and size the opportunity in numbers — an approximate, well-justified number beats a precise one with no reasoning.

Stage 2 — Decision logic

The heart of the case: who to target (and who's excluded), through which channel — WhatsApp, SMS or push, each with different cost and open rates — the rule that ties cost to expected return, and a guardrail that stops a miscalibration from burning money or wearing out the base.

Stage 3 — Working prototype

A navigable web app, loaded with the Retail Base and Customer Base data, that someone on the Growth team could actually use to build and evaluate a campaign — without you explaining it alongside. Use whatever tool you like. Deliver the working app link + the code repository.

Stage 4 — Proof and handoff

How you'd measure whether it worked (the metric, how to isolate the real effect, and the kill criterion if it doesn't pan out) + a short handoff for two audiences: **business** (what value the solution delivers, what Growth can now do that it couldn't before) and **engineering** (how it works at a high level, what's no-code versus what would need engineering to scale).

Deliverables summary

#	Deliverable
1	Short write-up covering Framing, Reading the data, Decision logic, and Proof & Handoff — including a short decision log (what you tested, what you discarded, and why).

There's no required template. Organize it however feels clearest.

Deadline and delivery

5 business days from when you receive this document

One single deadline — no intermediate delivery step. Punctuality and the quality of your interactions along the way (questions asked, assumptions validated) are also signals we evaluate.

Questions are welcome and expected. The data is intentionally incomplete — you'll likely find information missing that you want. If you need context, want to validate an assumption, or notice something missing from the data, reach out directly. A good builder doesn't stay stuck on an assumption they could have validated with a question.

Good luck.
